Weeko4 - Part 01

Before we start, some announcements:

1. We cannot change the tutorial times.

2-WS solutions will be posted weekly (on the Wednesday of the tutorials). This gives you time to work on the WS on your own and test/improve your undestanding

3-A list of useful documents to review probability, linear algebra, and matrix (alculus is posted on course page.

4. You MVST write your own solution to each week's WS before checking the Solutions and going to totoricals.

This is the only way to learn. You do not need to submit your solutions.

Week04 - Part 01

Last week Recorp: Logistic Regression & Gradient de scent We sow the activition function and log-loss function. We sow the Maximum likelihood and Cros-Entropy Minimization interperetation af minimizing leg-loss. We don't house a closed form Solution for minimizing the elg-loss tinction Hence, We used gradient descent to numerically find the minimizer $g_t = -\nabla f(x_t)$ $2L_{t+1} = 2L_t + E_t g_t$

A Qvick Real Before We Move On

Recall: Let f: R->R and g: R->R. Then

$$\nabla_{\mathbf{z}} g(f(\mathbf{z})) =$$

E.g.: $\nabla_{\mathbf{x}} \left(1 + \log (\underline{a}^{\mathsf{T}} \underline{x}) \right)^2 =$

Homework: Prove the chain rule.

Using Gradient Descent for Legistic Regression

Logistic Regression in Sample Error: $E_{in}(w) = \frac{1}{N} \sum_{n=1}^{N} e_n(w) = \frac{1}{N} \sum_{n=1}^{N} log(1 + e^{-y_n w^T N_n})$

Thus, Gradient Descent would update Wt by $\mathcal{G}_t = -\nabla E_{in}(\underline{w}_t) = -\frac{1}{N} \sum_{n=1}^{N} \nabla e_n(\underline{w}_t).$ $W_{t+1} = W_t + \varepsilon_t g_t$ ■ Good News: Fil It can be shown that $\frac{1}{N}\sum_{n=1}^{N}\log\left(1+e^{-y_nw^{T}x_n}\right)$ is Connex. Bad News: To run one iteration of Gradient Descent, we need to find $\nabla_{w_t} P(w_t)$ for all $n \in \{1, 2, ..., N\}$ points. This is Costly, Specially when N is large (big data).

16

Stochastic Gradient Descent (560)

Gradient Descent (GD): $W_{t+1} = W_t - \mathcal{E}_t \cdot \nabla_w \mathcal{E}_{in} [W_t]$. The averge gradient $\nabla_w \mathcal{E}_{in} [W_t]$ of the points $\nabla_w \mathcal{E}_{in} [W_t]$. The averge $\nabla_w \mathcal{E}_{in} [W_t]$ of $\nabla_w \mathcal{E}_{in} [W_t]$. Stochastic Gradient Descent (560): In each iteration,

日

马

But does it work?

Fir It has been proven that for Gover functions and Under mild Conditions, SGD will find the Solution.
Fil Don't worry about the proof. Don't wormy about the conditions.

Note 1: 9t of 560 is an Unbiased estimate of VEn(we)

Let's study the expected update direction derived by SGD in each Step.

 $\mathbb{E}\left[\tilde{a}^{\dagger}\right]$

Note 2: Full GD Complexity V.S. SGD Complexity Full GD ("botch GD"): Per iteration complexity is 叶 SGD: Per iteration Complexity is 41 Complexity of 1911 iteration of SGD = Complexit of 1 iteration of GD

Note 3: "Mini-batch" GD is full-batch GD Compined with SGD

- mini-batch GD; In each iteration;
- choose M Sample 1, r, r, r, E }1, ..., Ny uniformly at random
- $g_t = \frac{1}{M} \sum_{i=1}^{M} \nabla e_{r_i}(y_t)$
- · WtH = Wt + Et gt
- Benefits:

4

PLA is An Extremer Version of Logistic Regression with SGO

ligistic regression with SGD updates:

$$\nabla e_n(w_t) = \frac{-g_n z_n}{1 + e^{g_n w_t^T z_n}}$$

and $W_{t+1} = W_t + \varepsilon_t = \frac{y_n z_n}{1 + e^{y_n w_t^T z_n}}$

When we randomly pick some 2c, which is misclassified

I y, w, x, <0 > 0 < e y, w, xn < 1

The SGD update would be $w_{t+1} = w_t + \frac{\mathcal{E}_t}{1 + e^{y_n w_t^T x_n}} \cdot (y_n x_n)$

Fig. In extreme Case, $e^{g_n \cdot y_t^T x_n} \approx 0$ and the update rule would be $W_{t+1} \approx W_t + \mathcal{E}_t (y_n \cdot x_n)$ (Same as PIA if $\mathcal{E}_t = 1$.)

When we roundowly pick some $2C_n$ which is correctly classified.

To $y_n w_t^T x_n > 0 \implies 1 \le 2C_n w_t^T x_n$ The SGD update would be $2C_{t+1} = W_t + \frac{\mathcal{E}_t}{1 + e^{y_n w_t^T x_n}} \cdot (y_n x_n)$ Film extrem Cose, 1+e Junt 100 and the update rule would be

With $\approx w_t$ Same as PIA as it does not

update w for Greetly classified points
